## RESUME

Operator: Meridian Oil, Incorporated

Well Name and Number: 41-27 Buckskin Mesa Unit

Field: Powell Park

Location: NW NE NE Section 27, T-1N, R-95W

County and State: Rio Blanco, Colorado

Elevation: GL: 6036', KB: 6048'

Spud Date: December 9, 1994

Completion Date: December 16, 1994

Hole Sizes: 8 3/4": 50-520'; 6 1/4": 520-4230'

Casing Data: 7", 20 lb/ft, set at 516'; cemented with 100 sx

Logging Data: DSN/CDL/DISGL/GR, LSS/GGR/CAL; HLS, Vernal

Development Geologist: Ward Whiteman

Drilling Foreman: Roy Neset

Wellsite Geologist: John C. Lamb

Contractor: Elenburg, Rig 15

Tool Pusher: Burt Huntington

Mud Type: Chem-Gel

Mud Company: Bariod, Sam Willis

Drilling Days: 8

Rotating Hours: 90 1/4

Bottom Formation: Ohio Creek

Status: Dry and Abandoned

### SUMMARY

The 41-27 Buckskin Mesa Unit was drilled at the Powell Park Field as a development well. The primary objective were the Basal Wasatch Ohio Creek Sandstones, the secondary objective was to evaluate the potential of sandstone development within the Upper Wasatch. Nearby well control had previously established gas production from both the primary and secondary objectives. The location, which was not on a seismic line, was selected upon the basis of geological interpretation.

Within the Ohio Creek, the gas productive sandstone that was present in the offsetting Phillips-Trident Mannel #1, was not developed at this location. Non productive sample and hot wire hydrocarbon shows were encountered within two intervals in the Ohio Creek (3580-3595', 3630-3670').

The uppermost, in which a 600 unit gas peak was registered, was readily apparent in the samples and was described as a large increase in smaller clusters: white to semi translucent, salt and pepper appearance, upper fine grain, sub round, well sorted, very poorly consolidated, very friable to slightly soft, slightly to moderately clay filled, occasionally clean appearing, heavy amount carbonaceous and shale clasts, fair porosity, predominately with very dull faint greenish fluorescence and very faint crush cut.

The lowermost show, through which a 310 unit gas peak was registered; was also readily apparent in the samples. The sandstone was described as a coarsening downward sequence: general increase in amount of sandstone, predominately smaller clusters with frequent unconsolidated grains; unconsolidated: translucent to opaque, lower medium and coarse grain, sub angular, very poorly sorted, occasional chert grains; smaller clusters: semi translucent to light grayish, slightly salt and pepper appearance, upper fine to medium with an increase in coarse grains with depth, sub angular, very poor to poorly sorted, very poorly consolidated, very friable, generally moderately clay filled, frequent feldspar, chert grains and shale clasts, general increase in cleaner clusters with slightly spotty to even, dull to moderately bright green fluorescence; occasionally with bright, pinpoint green fluorescence, fair sub streaming green cut.

Within the Upper Wasatch, the sandstone bench from which gas is produced in the offsetting well, the MOI 11-26 Bradfield; was not deposited at this location. However, two hot wire shows were encountered in the Upper Wasatch (1180-1190' & 1576-1600').

The uppermost, a 320 unit increase over a zero background was accompanied in the samples by a trace only of unconsolidated grains. The zone, which yielded increases of produced gas initially as high as 2000 units, was no longer yielding increases after approximately two hundred feet had been drilled. Electric logs show a thin sandstone at 1990-1194' that is bounded by thin washouts on either side.

The subsequent hot wire show in the Upper Wasatch was a seven hundred fifty unit peak over a ten unit background. The gas increase was accompanied by a sample show in sandstone: larger and smaller clusters, semi translucent to off white, fine to lower medium grain, occasional upper medium grain, poorly sorted, poorly consolidated, friable to very friable, slightly to moderately clay filled, scattered feldspar grains and carbonaceous clasts, poor to fair porosity; frequently with dull, uneven greenish fluorescence, faint greenish yellow crush cut.

Within the Lower Wasatch, three hot wire shows were encountered (2530-2540', 3065-3080', 3405-3420'). The uppermost was a four hundred and fifty unit peak over a fifty unit background. It was accompanied by a very weak sample show; smaller clusters: semi translucent, lower to upper fine grain, sub round, fair sorted, poorly consolidated, very friable to brittle, slightly clay filled, fine carbonaceous clasts and feldspar grains, poor to fair porosity; rarely with dull greenish fluorescence and weak crush cut.

The second gas show in the Lower Wasatch was a five hundred and twenty five unit increase over a ten unit background and was not accompanied by a sample show. The zone did yield produced gas increases until the next liberated gas show was encountered. Description: predominately smaller clusters: translucent to semi translucent white, lower to upper fine grain, sub round, fair sorted, very poor consolidated, very friable, spotty to even clay filled, poor to occasional fair porosity.

The third gas show within the Lower Wasatch was three hundred and ninety unit peak over a fifty five unit background and was accompanied by a sample show. Description: heavy amount smaller clusters: translucent upper fine to medium grain with occasional coarse grain, sub round, very poorly consolidated, very friable, scattered feldspar grains, generally slightly to moderately clay filled, fair to good porosity; generally with dull to moderately bright, even to slightly spotty greenish fluorescence with a weak sub streaming to milky in part green cut. Frequent unconsolidated grains were also described: clear, fine to medium to lower coarse grain, sub angular to sub round, poorly sorted.
